Abstract

The dominant electroweak corrections to the production cross sections and partial decay widths of a light Standard-Model Higgs boson, with mass $M_H \ll 2m_t$, are due to top-quark loops. By means of a low-energy theorem, we study at the two-loop level the leading shifts in the Higgs-boson couplings to pairs of light fermions and gauge bosons induced by a sequential isodoublet of high-mass fermions. For tree-level and loop-induced Higgs-boson couplings, these corrections are of relative orders $\mathcal{O}(G_\mu^2 m_F^4)$ and $\mathcal{O}(G_\mu m_F^2)$, respectively, where m_F represents a generic heavy-fermion mass, with $m_F \gg M_W, M_H$. Except for the $Hb\bar{b}$ coupling, all results carry over to the case of the top-quark-induced corrections. We discuss possible phenomenological consequences of our results.

1 Introduction

The Higgs boson is the last missing link of the Standard Model (SM) of elementary particle physics. Its experimental discovery would eventually solve the longstanding puzzle as to whether nature makes use of the mechanism of spontaneous symmetry breaking to generate the particle masses. So far, direct searches at the CERN Large Electron Positron Collider (LEP) have been able to rule out the mass range $M_H \leq 77.1$ GeV at the 95% confidence level (CL) [1]. On the other hand, exploiting the sensitivity to the Higgs boson via quantum loops, a global fit to the latest electroweak precision data predicts $M_H = 115^{+116}_{-66}$ GeV together with a 95% CL upper bound at 420 GeV [2]; see also the discussion in Ref. [3].

The study of quantum corrections to the production and decay processes of the Higgs boson has received much attention in the literature; for a review, see Ref. [4]. In the following, we shall consider a light-Higgs-boson scenario, characterized by $M_H \ll 2m_t$. Such a situation is not only favored experimentally [2, 3], but also from various theoretical considerations [5, 6]. For example, the requirement that the running Higgs self-coupling, $\lambda(\mu)$, does not develop a Landau pole for renormalization scales $\mu < \Lambda_{\text{GUT}} \approx 10^{16}$ GeV leads to the triviality bound $M_H \lesssim 185$ GeV [5]. Since the top quark, with pole mass $m_t = (175.6 \pm 5.5)$ GeV [7], is much heavier than the intermediate bosons, top-quark loop effects tend to be the dominant source of electroweak corrections to the couplings of a light Higgs boson. The goal of this paper is to calculate the leading m_t -dependent corrections at two loops to the Higgs-boson couplings to gauge bosons and light fermions. For the time being, we shall leave aside the bottom and top Yukawa couplings as well as the Higgs-boson self-couplings.

For the discussion of the leading m_t -dependent corrections, it is useful to distinguish between the Higgs-boson couplings that already exist at tree level, such as the $Hf\bar{f}$, HWW and HZZ couplings, and those which are induced by heavy-particle loops, such as the $H\gamma\gamma$, $H\gamma Z$ and Hgg couplings. The present knowledge of the higher-order radiative corrections to the couplings of the first type is as follows. The complete one-loop calculation of the $Hf\bar{f}$ and HVV couplings, where $V = W, Z$, has been carried out in Refs. [8, 9] and [8, 10], respectively. The two-loop $\mathcal{O}(\alpha_s G_\mu m_t^2)$ corrections to the light-fermion and bottom Yukawa couplings have been calculated in Refs. [11, 12] and [13], respectively, and those to the HVV couplings in Ref. [14]. The three-loop $\mathcal{O}(\alpha_s^2 G_\mu m_t^2)$ corrections may be found in Ref. [15] for the Hl^+l^- and HVV couplings and in Ref. [16] for the $Hq\bar{q}$ couplings, including the $b\bar{b}$ case. As for the loop-induced Higgs-boson vertices, the two-loop QCD corrections to the $H\gamma\gamma$, $H\gamma Z$ and Hgg couplings have been derived in Refs. [17, 18, 19], respectively. The three-loop $\mathcal{O}(\alpha_s^2)$ corrections to the $H\gamma\gamma$ and Hgg and couplings have been found in Refs. [20, 21] and [22], respectively; this analysis has also been extended to $\mathcal{O}(\alpha_s^3)$ [21]. The leading two-loop electroweak corrections, which

are of $\mathcal{O}(G_\mu m_t^2)$ relative to the one-loop result, have only been calculated in the case of the Hgg coupling [23].

The leading electroweak two-loop corrections of $\mathcal{O}(G_\mu^2 m_t^4)$ to the $Hf\bar{f}$ and HVV couplings, as well as the two-loop $\mathcal{O}(G_\mu m_t^2)$ corrections to the $H\gamma\gamma$ and $H\gamma Z$ couplings are not yet available. In this paper, we shall partly fill these gaps. For the sake of generality, we shall consider a sequential fourth-generation fermion doublet with arbitrary masses $m_A, m_B \gg M_W, M_H$. The results for the top-quark-induced corrections then emerge by substituting $m_A = m_t$ and $m_B = 0$. Notice, however, that there is an additional class of diagrams contributing to the $\mathcal{O}(G_\mu^2 m_t^4)$ corrections to the $Hb\bar{b}$ coupling, which is absent in the fourth-generation case. These bottom-specific corrections will not be considered here.

The study of the extension of the SM by a fourth fermion generation is interesting in its own right. Recently, it was noticed [24] that arguments favoring the presence of a fourth fermion generation may be adduced on the basis of the democratic mass-matrix approach [25]. The possible existence of a fourth fermion generation is also considered in the Review of Particle Physics [26], where mass bounds are listed. For a recent model-independent analysis, see Ref. [27]. It is advantageous to trace such novel fermions via their loop effects in the Higgs sector, since these effects are also sensitive to mass-degenerate isodoublets via fermion-mass power corrections. This has originally been observed in Ref. [8] in connection with the $Hf\bar{f}$, HWW and HZZ couplings. Moreover, the $H\gamma\gamma$ and Hgg couplings may serve as devices to detect mass-degenerate isodoublets of ultraheavy fermions [28], although power corrections do not occur here at leading order. By contrast, in the gauge sector, leading power corrections only appear in connection with isospin breaking [29].

Since, at this point, we only wish to extract the leading heavy-fermion corrections to the Higgs-boson couplings, we may work in the framework of a Yukawa Lagrangian where the heavy fermions only couple to the Higgs boson and the longitudinal components of the gauge bosons, a situation which corresponds to the *gaugeless limit* of the SM [30]. In the presence of external gauge bosons, these can be considered as background sources. In practice, in the covariant gauges, it suffices to only consider the diagrams that involve exchanges of scalar bosons. However, this simple approach may fail if there is a symmetry which lowers the superficial degree of divergence of the loops. For instance, this happens in the case of the $H\gamma\gamma$ coupling, where QED Ward identities imply that W -boson loops cannot be neglected any more. Nevertheless, we will show that, also in this case, the calculation can be performed in a very compact manner. Moreover, we may also take advantage of a soft-Higgs theorem [31, 32], extended to higher-orders [33], which relates the couplings of the Higgs boson to gauge bosons to derivatives of the vacuum-polarization functions of the latter.

This paper is organized as follows. In the next section, we will analyze the universal

$\mathcal{O}(G_\mu^2 m_F^4)$ correction to the Higgs-boson vertices. This is the only such contribution in the case of the lepton and light-quark Yukawa couplings, except for the $Hb\bar{b}$ coupling. The results will be presented both in the electroweak $\overline{\text{MS}}$ [34] and on-shell [35, 36] schemes. In Section 3, we will derive the $\mathcal{O}(G_\mu^2 m_F^4)$ corrections to the HWW and HZZ couplings. In Section 4, we will turn to the couplings which are not present at tree level, and calculate the two-loop $\mathcal{O}(G_\mu m_F^2)$ corrections to the loop-induced $H\gamma\gamma$ and Hgg couplings. Finally, Section 5 is devoted to the numerical discussion of our results.

2 Universal correction: $Hf\bar{f}$ couplings

At leading order in the heavy-fermion masses, i.e. to $\mathcal{O}(G_\mu m_F^2)$ at one loop and to $\mathcal{O}(G_\mu^2 m_F^4)$ at two loops for couplings present at the tree level, one can isolate an ultraviolet-finite and gauge-invariant contribution to the Higgs-boson production and decay amplitudes which is universal in the sense that it is independent of the initial and final states. As for the Yukawa couplings of the leptons and light quarks, except for the bottom quark, this is the only source of leading top-quark contributions. In this section, we will discuss this universal correction in the more general case of an isodoublet of heavy fermions, first in the electroweak $\overline{\text{MS}}$ scheme of Ref. [34] and then in the on-shell scheme. The scheme of Ref. [34] uses $\overline{\text{MS}}$ couplings and on-shell masses as basic parameters.

The bare Lagrangian describing the interactions of the Higgs boson with fermions f and intermediate bosons $V = W, Z$,

$$\mathcal{L} = \frac{H_0}{v_0} \left(- \sum_f m_{f0} \bar{f}_0 f_0 + 2M_{W0}^2 W_{0\mu}^\dagger W_0^\mu + M_{Z0}^2 Z_{0\mu} Z_0^\mu \right), \quad (1)$$

contains the overall factor H_0/v_0 , where H the Higgs field, v is the vacuum expectation value and the subscript 0 labels bare quantities. This ratio undergoes a finite renormalization. Recalling that $v_0 = 2M_{W0}/g_0 = 2c_0 M_{Z0}/g_0$, where g is the $\text{SU}(2)_L$ coupling constant and c is the cosine of the weak mixing angle, we define the finite universal shift in the $\overline{\text{MS}}$ scheme, $\hat{\delta}_u$, via

$$\frac{H_0}{v_0} = \frac{\hat{g}H}{2\hat{c}M_Z} (1 + \hat{\delta}_u), \quad (2)$$

where $\hat{g}$ and $\hat{c}$ are defined in the $\overline{\text{MS}}$ scheme and M_Z is the physical Z -boson mass defined as the real part of the pole of the propagator. Shifting M_{Z0}^2 and H_0 , one obtains

$$\frac{H_0}{v_0} = \frac{\hat{g}H}{2\hat{c}M_Z} \left(1 - \frac{\delta M_Z^2}{M_Z^2} \right)^{-1/2} \left[1 + \text{Re} \Pi'_{HH}(M_H^2) \right]^{-1/2}, \quad (3)$$

where $\delta M_Z^2 = \text{Re } A_{ZZ}(M_Z^2)$, $A_{ZZ}(q^2)$ is the Z -boson self-energy and $\Pi_{HH}(q^2)$ is the Higgs-boson self-energy, defined according to the conventions of Ref. [11, 12]. Since we are only interested in the leading $\mathcal{O}(G_\mu m_F^2)$ and $\mathcal{O}(G_\mu^2 m_F^4)$ corrections, we may replace $\text{Re } A_{ZZ}(M_Z^2)$ and $\text{Re } \Pi'_{HH}(M_H^2)$ in Eq. (3) with $A_{ZZ}(0)$ and $\Pi'_{HH}(0)$, respectively. In the $\overline{\text{MS}}$ scheme, as a consequence of the SU(2) custodial symmetry of the SM, the counterterm $\delta\hat{c}^2 = -\hat{c}^2[\delta M_W^2/M_W^2 - \delta M_Z^2/M_Z^2]_{UV}$, where the subscript UV indicates that only the ultraviolet pole has to be considered, receives no quadratic fermion-mass contributions [34]. Hence, the counterterms for $\hat{c}$ and $\hat{g}$ do not contain leading-order contributions in the heavy-fermion masses. This is the reason why we first present our results in this particular scheme. Denoting one- and two-loop contributions by the superscripts (1) and (2), respectively, we may identify the $\mathcal{O}(G_\mu m_F^2)$ contribution to $\hat{\delta}_u$ as

$$\hat{\delta}_u^{(1)} = \frac{1}{2} \frac{\delta^{(1)} M_Z^2}{M_Z^2} - \frac{1}{2} \Pi_{HH}^{(1)'}(0). \quad (4)$$

The one-loop $\mathcal{O}(G_\mu m_F^2)$ contribution from a weak isodoublet of ultraheavy fermions, with arbitrary masses m_A , m_B and color multiplicity N_c , to the Z -boson mass counterterm and the Higgs-boson wave-function renormalization constant (see Fig. 1a) are given by

$$\frac{\delta^{(1)} M_Z^2}{M_Z^2} = \frac{N_c g_0^2}{16\pi^2 c_0^2 M_Z^2} \sum_{F=A,B} m_{F0}^2 \left(\frac{\mu}{m_{F0}} \right)^{2\epsilon} \left[\frac{1}{2\epsilon} + \frac{\pi^2}{24} \epsilon + \mathcal{O}(\epsilon^2) \right], \quad (5)$$

$$\Pi_{HH}^{(1)'}(0) = \frac{N_c g_0^2}{16\pi^2 c_0^2 M_{Z0}^2} \sum_{F=A,B} m_{F0}^2 \left(\frac{\mu}{m_{F0}} \right)^{2\epsilon} \left[\frac{1}{2\epsilon} - \frac{1}{3} + \frac{\pi^2}{24} \epsilon + \mathcal{O}(\epsilon^2) \right], \quad (6)$$

respectively. Here, $n = 4 - 2\epsilon$ is the space-time dimension in dimensional regularization, μ the 't Hooft renormalization scale and we have kept the $\mathcal{O}(\epsilon)$ terms for later convenience. Inserting Eqs. (5,6) into Eq. (4), one obtains

$$\hat{\delta}_u^{(1)} = \frac{N_c \hat{g}^2 m_A^2}{16\pi^2 \hat{c}^2 M_Z^2} \frac{1+x}{6}. \quad (7)$$

Here and in the following, $x = m_B^2/m_A^2$.

We now extend the analysis to the two-loop level keeping only the leading $\mathcal{O}(G_\mu^2 m_F^4)$ terms. Our starting point is the two-loop analogue of Eq. (4),

$$\hat{\delta}_u^{(2)} = \frac{1}{2} \frac{\delta^{(2)} M_Z^2}{M_Z^2} - \frac{1}{2} \Pi_{HH}^{(2)'}(0) + \delta_u^{\text{ct}} + \frac{1}{2} \frac{\delta^{(1)} M_Z^2}{M_Z^2} \Pi_{HH}^{(1)'}(0) + \frac{3}{2} \left(\hat{\delta}_u^{(1)} \right)^2. \quad (8)$$

Here, the first two terms represent the irreducible two-loop contributions to the Z -boson mass counterterm and the Higgs-boson wave-function renormalization constant to be calculated below. The third term arises because part of the one-loop contribution of Eq. (7)

is expressed in terms of bare quantities, namely the fermion masses in Eqs. (5,6) and the Z -boson mass in Eq. (6), while the one appearing in Eq. (5) is renormalized by definition. The counterterms associated with the couplings can be neglected, as they do not contain leading terms in the $\overline{\text{MS}}$ scheme. The last two terms in Eq. (8) represent iterations of the one-loop contributions.

At this point, it is useful to separate $\hat{\delta}_u^{(2)}$ in two parts: one which is proportional to N_c and includes all irreducible two-loop contributions along with the respective fermion mass counterterms; and one which is proportional to N_c^2 and comes from the iteration of the one-loop terms including the Z -boson mass counterterms. The two sets of contributions must be independently finite and gauge invariant. As the calculation is performed in n dimensions, $\mathcal{O}(\epsilon)$ terms must generally be kept in the one-loop expressions. We first consider the subset of contributions proportional to N_c^2 . Shifting the bare Z -boson mass in Eq. (6), one obtains a term which exactly cancels the fourth term in Eq. (8). Thus, the only contribution proportional to N_c^2 arises from the last term in Eq. (8), with $\hat{\delta}_u^{(1)}$ given by Eq. (7).

As for the contributions proportional to N_c , let us first consider the heavy-fermion mass counterterms (see Fig. 1b). Since m_A and m_B only enter at one loop, it is sufficient to know these counterterms to $\mathcal{O}(G_\mu m_F^2)$. If the fermion masses are renormalized on shell, we have

$$\begin{aligned} \frac{\delta m_A}{m_A} = & \frac{\hat{g}^2 m_A^2}{16\pi^2 \hat{c}^2 M_Z^2} \left(\frac{\mu}{m_A} \right)^{2\epsilon} \left[-\frac{3(1-x)}{8\epsilon} - \frac{8-5x+x^2}{8} - \frac{x^2}{8}(3-x) \ln x \right. \\ & \left. + \frac{(1-x)^3}{8} \ln |1-x| + \mathcal{O}(\epsilon) \right]. \end{aligned} \quad (9)$$

The corresponding expression for $\delta m_B/m_B$ emerges by interchanging $A \leftrightarrow B$. Since $\hat{\delta}_u^{(1)}$ in Eq. (7) is a finite quantity, we do not need the $\mathcal{O}(\epsilon)$ parts of the fermion mass counterterms. However, it is necessary to retain the $\mathcal{O}(\epsilon)$ piece in the bare analogue of Eq. (7), since it combines with $\mathcal{O}(1/\epsilon)$ terms of the bare fermion masses contained therein to give finite two-loop contributions. With the help of Eqs. (5,6,9), we thus find

$$\delta_u^{\text{ct}} \doteq \frac{(1-x)^2}{8\epsilon} + \frac{3-2x+3x^2}{12} + \frac{x}{24}(3-2x-x^2) \ln x + \frac{(1-x)^4}{24x} \ln |1-x|. \quad (10)$$

Throughout Sections 2 and 3, the symbol $\doteq$ indicates that the right-hand side is to be multiplied by the overall factor

$$\frac{N_c \hat{g}^4 m_A^4}{(16\pi^2)^2 \hat{c}^4 M_Z^4} \left(\frac{\mu}{m_A} \right)^{4\epsilon}, \quad (11)$$

where $\epsilon = 0$ if finite results are concerned.

We now consider the irreducible two-loop contributions to $\hat{\delta}_u^{(2)}$, i.e. the first two terms of Eq. (8), which all scale like N_c . Typical Feynman diagrams are depicted in Fig. 2. We work in the R_ξ gauge and take γ_5 to be anticommuting. Since we are only interested in the leading $\mathcal{O}(G_\mu^2 m_F^4)$ terms, we may set the Higgs- and intermediate-boson masses as well as the external momentum squared to zero from the beginning. The actual calculation is conveniently performed with the aid of the symbolic manipulation program package *ProcessDiagram* [37]. Since all trilinear scalar-boson vertices, which are proportional to the scalar-boson masses, are set to zero from the beginning, only the diagrams with four Yukawa couplings contribute to the Higgs-boson self-energy in leading order (see Fig. 2a). The Higgs-boson wave-function renormalization constant is found to be

$$\begin{aligned} \Pi_{HH}^{(2)'}(0) &\doteq -\frac{3(1-x)^2}{16\epsilon^2} + \frac{1}{\epsilon} \left[\frac{11-38x+11x^2}{32} - \frac{3}{8}x(1-x)\ln x \right] \\ &\quad + \frac{17-2x+17x^2}{192} - \frac{\pi^2}{32}(1-x)^2 + \frac{x}{16}(19-11x)\ln x \\ &\quad + \frac{x}{16}(3-5x)\ln^2 x - \frac{(1-x^2)}{8}\text{Li}_2(1-x) + \mathcal{O}(\epsilon), \end{aligned} \quad (12)$$

where $\text{Li}_2(x) = -\int_0^1 dt \ln(1-xt)/t$ is the Spence function.

In the limit we are considering, the Z -boson mass counterterm only receives contributions from diagrams which contain no internal vector-boson lines and at least one scalar-boson line (see Fig. 2b). Some of these diagrams are infrared divergent because we have set the masses of the Higgs and Goldstone bosons to zero. One can regulate these divergences in different ways, for instance by using dimensional regularization or by assigning small masses to these scalar bosons, which may be different or the same. Note that, in the Lagrangian under consideration, there is no symmetry which protects the masslessness of the scalar bosons, so that these masses receive radiative corrections, which are also of $\mathcal{O}(G_\mu^2 m_F^4)$. Since these contributions are linked to the tadpole counterterms via Ward identities, as explained e.g. in the Appendix of Ref. [11], we can equivalently view them as keeping the Goldstone bosons massless. Therefore, we still need to add the counterterm contributions which emerge by shifting the scalar-bosons masses in the one-loop seed diagrams. These contributions are themselves infrared divergent, but if they are combined with the irreducible two-loop diagrams, the result is infrared regular and independent of the regularization adopted, as it should be. The use of a small mass regulator common to all the scalar bosons is particularly convenient, since it quenches the counterterm contribution. In this way, we find for $\delta^{(2)} M_Z^2/M_Z^2$, including the scalar-boson mass-counterterm contributions,

$$\begin{aligned} \frac{\delta^{(2)} M_Z^2}{M_Z^2} &\doteq -\frac{3(1-x)^2}{16\epsilon^2} + \frac{1}{\epsilon} \left[\frac{3-22x+3x^2}{32} - \frac{3}{8}x(1-x)\ln x \right] \\ &\quad + \frac{19}{64}(1-x)^2 - \frac{\pi^2}{32}(1-x)^2 + \frac{x}{16}(11-3x)\ln x \end{aligned}$$

$$+\frac{x}{16}(3-5x)\ln^2 x - \frac{1-x^2}{8}\text{Li}_2(1-x) + \mathcal{O}(\epsilon). \quad (13)$$

Inserting Eqs. (7,10,12,13) into Eq. (8), we finally obtain the universal correction at two loops in the $\overline{\text{MS}}$ scheme as

$$\hat{\delta}_u^{(2)} \doteq \frac{17-22x+17x^2}{48} - \frac{x}{24}(3-4x+x^2)\ln x + \frac{(1-x)^4}{24x}\ln|1-x| + \frac{N_c}{24}(1+x)^2. \quad (14)$$

In the limiting cases $m_A \gg m_B$ and $m_A \approx m_B$, this becomes

$$\hat{\delta}_u^{(2)}\big|_{x=0} \doteq \frac{5}{16} + \frac{N_c}{24}, \quad \hat{\delta}_u^{(2)}\big|_{x=1} \doteq \frac{1}{4} + \frac{N_c}{6}, \quad (15)$$

respectively.

In the next section, we will also need the leading contribution from an ultraheavy fermion isodoublet to the W -boson mass counterterm $\delta M_W^2 = \text{Re } A_{WW}(M_W^2)$, which may be calculated in the same way as in the Z -boson case. At the one-loop order, it is given by

$$\begin{aligned} \frac{\delta^{(1)} M_W^2}{M_W^2} &= \frac{N_c g_0^2 m_A^2}{16\pi^2 M_W^2} \left(\frac{\mu}{m_A} \right)^{2\epsilon} \left\{ \frac{1+x}{2\epsilon} + \frac{1+x}{4} + \frac{x^2}{2(1-x)} \ln x \right. \\ &\quad \left. + \epsilon \left[\frac{1+x}{8} + \frac{\pi^2}{24}(1+x) + \frac{x^2}{4(1-x)} \ln x - \frac{x^2}{4(1-x)} \ln^2 x \right] \right\} + \mathcal{O}(\epsilon^2). \end{aligned} \quad (16)$$

The corresponding two-loop result, including the contributions due to the scalar-boson mass counterterms, is given by

$$\begin{aligned} \frac{\delta^{(2)} M_W^2}{M_W^2} &\doteq -\frac{3(1-x)^2}{16\epsilon^2} + \frac{1}{\epsilon} \left[-\frac{3-14x+3x^2}{32} + \frac{3x^2(3-x)}{8(1-x)} \ln x \right] \\ &\quad + \frac{69+14x+69x^2}{64} - \frac{\pi^2}{32}(1-x)^2 + \frac{x(14+31x-3x^2)}{16(1-x)} \ln x \\ &\quad - \frac{x^2(7-10x-x^2)}{16(1-x)^2} \ln^2 x - \frac{7}{8}(1-x^2)\text{Li}_2(1-x) + \mathcal{O}(\epsilon). \end{aligned} \quad (17)$$

Results in the on-shell scheme

So far, we have discussed the universal correction in the electroweak $\overline{\text{MS}}$ scheme of Ref. [34]. By contrast, in the electroweak on-shell scheme, the couplings are expressed in

terms of G_μ , M_W and M_Z . To the orders considered here, the relations between the $\overline{\text{MS}}$ couplings and on-shell parameters read [34]

$$\hat{c}^2 = \frac{M_W^2}{M_Z^2}(1 - \Delta\rho), \quad \hat{g}^2 = 4\sqrt{2}G_\mu M_W^2, \quad (18)$$

where

$$\Delta\rho = \frac{A_{ZZ}(0)}{M_Z^2} - \frac{A_{WW}(0)}{M_W^2} \quad (19)$$

embodies the leading fermionic correction to the electroweak ρ parameter. The one-loop heavy-fermion contribution to $\Delta\rho$ is well known and reads [29]

$$\Delta\rho^{(1)} = \frac{N_c G_\mu m_A^2}{8\pi^2 \sqrt{2}} \left(1 + x + \frac{2x}{1-x} \ln x \right). \quad (20)$$

We recall that this expression vanishes for degenerate fermion masses, as isospin violation is the only source of custodial symmetry breaking, which induces leading power corrections. On the other hand, $\Delta\rho^{(1)} = N_c G_\mu m_A^2 / (8\pi^2 \sqrt{2})$ if $m_A \gg m_B$. The two-loop contribution is obtained from the difference of Eqs. (13,17) as

$$\begin{aligned} \Delta\rho^{(2)} \doteq & \frac{11 - 12x + 11x^2}{8} + \frac{2 + x + 19x^2 - 9x^3 + 3x^4}{16(1-x)} \ln x \\ & + \frac{(1-x)^2}{16x} (3 - 2x + 3x^2) \ln |1-x| - \frac{x^3(3-x^2)}{8(1-x)^2} \ln^2 x \\ & + \frac{1-x}{8x} (1+x^3) \ln x \ln |1-x| - \frac{3}{4} (1-x^2) \text{Li}_2(1-x), \end{aligned} \quad (21)$$

which is in agreement with Ref. [38]. Again, the expression vanishes for $m_A = m_B$. On the other hand, for $m_A \gg m_B$, one has $\Delta\rho^{(2)} \doteq (19 - 2\pi^2)/16$.

In order to derive the universal contribution in the on-shell scheme, δ_u , we start from the identity

$$\frac{H_0}{v_0} = \frac{\hat{g}H}{2\hat{c}M_Z} (1 + \hat{\delta}_u) = 2^{1/4} G_\mu^{1/2} H (1 + \delta_u). \quad (22)$$

Using Eq. (18), we thus have

$$1 + \delta_u = (1 + \hat{\delta}_u) (1 - \Delta\rho)^{-1/2}. \quad (23)$$

At the one loop-level, this implies

$$\delta_u^{(1)} = \frac{N_c G_\mu m_A^2}{8\pi^2 \sqrt{2}} \left[\frac{7}{6} (1+x) + \frac{x}{1-x} \ln x \right], \quad (24)$$

which agrees with Refs. [8, 9]. Expanding Eq. (23) consistently through two loops, we obtain

$$\delta_u^{(2)} = \hat{\delta}_u^{(2)} + \frac{1}{2}\Delta\rho^{(2)} + \frac{1}{2}\hat{\delta}_u^{(1)}\Delta\rho^{(1)} + \frac{3}{8}\left(\Delta\rho^{(1)}\right)^2. \quad (25)$$

Inserting Eqs. (4,14,20,21), one then finds the universal correction in the electroweak on-shell scheme to be

$$\begin{aligned} \delta_u^{(2)} \doteq & \frac{25 - 29x + 25x^2}{24} + \frac{6 - 9x + 85x^2 - 47x^3 + 13x^4}{96(1-x)} \ln x \\ & + \frac{(1-x)^2}{96x} (13 - 14x + 13x^2) \ln |1-x| - \frac{x^3(3-x^2)}{16(1-x)^2} \ln^2 x \\ & + \frac{1-x}{16x} (1+x^3) \ln x \ln |1-x| - \frac{3}{8}(1-x^2) \text{Li}_2(1-x) \\ & + N_c \left[\frac{11}{128} (1+x)^2 + \frac{13x(1+x)}{96(1-x)} \ln x + \frac{3x^2}{32(1-x)^2} \ln^2 x \right], \end{aligned} \quad (26)$$

which, for $m_A \gg m_B$ and $m_A \approx m_B$, takes the values

$$\delta_u^{(2)} \Big|_{x=0} \doteq \frac{29}{32} - \frac{\pi^2}{16} + \frac{11}{128} N_c, \quad \delta_u^{(2)} \Big|_{x=1} \doteq \frac{1}{4} + \frac{N_c}{6}, \quad (27)$$

respectively. This completes the discussion of the universal contribution and the leading corrections to the lepton and light-quark Yukawa couplings.

3 The $HW W$ and HZZ couplings

We now turn to the leading electroweak corrections to couplings between Higgs and intermediate bosons. Since the $HW W$ and HZZ couplings appear already at the tree level, the leading one- and two-loop corrections in the heavy-fermion masses are of $\mathcal{O}(G_\mu m_F^2)$ and $\mathcal{O}(G_\mu^2 m_F^4)$, respectively.

In the electroweak $\overline{\text{MS}}$ scheme, the renormalized HVV interaction Lagrangian takes the form

$$\mathcal{L}_{HVV} = \frac{\hat{g}H}{\hat{c}M_Z} (1 + \hat{\delta}_u) \left[M_W^2 W_\mu^\dagger W^\mu (1 + \hat{\delta}_W) + \frac{M_Z^2}{2} Z_\mu Z^\mu (1 + \hat{\delta}_Z) \right], \quad (28)$$

where $\hat{\delta}_u$ is given by Eq. (14) and

$$1 + \hat{\delta}_V = (1 + \delta_V^{\text{irr}}) \left(1 - \frac{\delta M_V^2}{M_V^2} \right). \quad (29)$$

The appropriate one- and two-loop expressions for $\delta M_V^2/M_V^2$ may be found in Eqs. (5,13, 16,17). Notice that the wave-function renormalization constants of the intermediate bosons do not contribute to leading order in the heavy-fermion masses. The only missing piece in Eq. (28) is the irreducible HVV vertex correction, δ_V^{irr} . It can be derived by means of a low-energy theorem which relates the heavy-fermion contributions to the HVV vertex and VV self-energy corrections in the following way:

$$\delta_V^{\text{irr}} = \sum_{F=A,B} \frac{m_{F0}^2 \partial}{\partial m_{F0}^2} \frac{A_{VV}(0)}{M_{V0}^2}, \quad (30)$$

where it is understood that the masses appearing in coupling constants must be treated as constants under the differentiation [33].

In terms of bare parameters, the one-loop results for δ_V^{irr} through $\mathcal{O}(\epsilon)$ read

$$\begin{aligned} \delta_W^{\text{irr}(1)} &= \frac{N_c g_0^2 m_{A0}^2}{16\pi^2 M_{W0}^2} \left(\frac{\mu}{m_{A0}} \right)^{2\epsilon} \left\{ \frac{1+x_0}{2\epsilon} - \frac{1+x_0}{4} + \frac{x_0^2}{2(1-x_0)} \ln x_0 \right. \\ &\quad \left. + \epsilon \left[-\frac{1+x_0}{8} + \frac{\pi^2}{24}(1+x_0) - \frac{x_0^2}{4(1-x_0)} \ln x_0 - \frac{x_0^2}{4(1-x_0)} \ln^2 x_0 \right] + \mathcal{O}(\epsilon^2) \right\}, \\ \delta_Z^{\text{irr}(1)} &= \frac{N_c g_0^2}{16\pi^2 c_0^2 M_{Z0}^2} \sum_{F=A,B} m_{F0}^2 \left(\frac{\mu}{m_{F0}} \right)^{2\epsilon} \left[\frac{1}{2\epsilon} - \frac{1}{2} + \frac{\pi^2}{24}\epsilon + \mathcal{O}(\epsilon^2) \right]. \end{aligned} \quad (31)$$

Inserting Eqs. (5,16,31) into Eq. (29), we obtain the final one-loop results as

$$\begin{aligned} \hat{\delta}_W^{(1)} &= -\frac{N_c \hat{g}^2 m_A^2}{16\pi^2 M_W^2} \frac{1+x}{2}, \\ \hat{\delta}_Z^{(1)} &= -\frac{N_c \hat{g}^2 m_A^2}{16\pi^2 \hat{c}^2 M_Z^2} \frac{1+x}{2}. \end{aligned} \quad (32)$$

Expanding Eq. (29) and collecting the two-loop pieces, we have

$$\hat{\delta}_V^{(2)} = \delta_V^{\text{irr}(2)} - \frac{\delta^{(2)} M_V^2}{M_V^2} + \delta_V^{\text{ct}} - \delta_V^{\text{irr}(1)} \frac{\delta^{(1)} M_V^2}{M_V^2}. \quad (33)$$

As in case of δ_u^{ct} , the counterterm contribution, δ_V^{ct} , consists of two parts which scale as N_c and N_c^2 . They emerge by renormalizing the heavy-fermion and intermediate-boson masses, respectively, in the bare analogue of Eq. (32), $\hat{\delta}_V^{(1)} = \delta_V^{\text{irr}(1)} - \delta^{(1)} M_V^2/M_V^2$, where $\delta_V^{\text{irr}(1)}$ is given in Eq. (31) and $\delta^{(1)} M_V^2/M_V^2$ in Eqs. (5,16). The part proportional to N_c^2 exactly cancels against the last term on the right-hand side of Eq. (33). The part proportional to N_c is obtained by shifting the fermion masses in the bare version of $\hat{\delta}_V^{(1)}$ according to

Eq. (9) and reads

$$\begin{aligned}\delta_W^{\text{ct}} &\doteq -\frac{3(1-x)^2}{8\epsilon} - \frac{15-26x+15x^2}{16} + \frac{x^2(8-x-x^2)}{8(1-x)} \ln x - \frac{(1-x)^4}{8x} \ln|1-x| + \mathcal{O}(\epsilon), \\ \delta_Z^{\text{ct}} &\doteq -\frac{3(1-x)^2}{8\epsilon} - \frac{3-2x+3x^2}{4} - \frac{x}{8}(3-2x-x^2) \ln x - \frac{(1-x)^4}{8x} \ln|1-x| + \mathcal{O}(\epsilon).\end{aligned}\tag{34}$$

Again, the knowledge of the $\mathcal{O}(\epsilon)$ term in Eq. (9) is not required, as Eq. (32) does not contain ultraviolet divergences.

When we apply Eq. (30), we must differentiate with respect to the fermion masses which enter through the propagators and treat those coming from the Yukawa couplings as constants. We thus obtain

$$\begin{aligned}\delta_W^{\text{irr}(2)} &\doteq -\frac{3(1-x)^2}{16\epsilon^2} + \frac{1}{\epsilon} \left[\frac{9-10x+9x^2}{32} + \frac{3x^2(3-x)}{8(1-x)} \ln x \right] \\ &\quad + \frac{3}{64}(27-14x+27x^2) - \frac{\pi^2}{32}(1-x)^2 + \frac{x(14-5x+9x^2)}{16(1-x)} \ln x \\ &\quad - \frac{x^2(7-10x-x^2)}{16(1-x)^2} \ln^2 x - \frac{7}{8}(1-x^2) \text{Li}_2(1-x) + \mathcal{O}(\epsilon), \\ \delta_Z^{\text{irr}(2)} &\doteq -\frac{3(1-x)^2}{16\epsilon^2} + \frac{1}{\epsilon} \left[\frac{15-46x+15x^2}{32} - \frac{3}{8}x(1-x) \ln x \right] \\ &\quad + \frac{7+50x+7x^2}{64} - \frac{\pi^2}{32}(1-x)^2 + \frac{x}{16}(23-15x) \ln x \\ &\quad + \frac{x}{16}(3-5x) \ln^2 x - \frac{1-x^2}{8} \text{Li}_2(1-x) + \mathcal{O}(\epsilon).\end{aligned}\tag{35}$$

Combining the previous results, we finally obtain for the complete two-loop correction to the HWW and HZZ couplings in the $\overline{\text{MS}}$ scheme

$$\begin{aligned}\hat{\delta}_W^{(2)} &\doteq -\frac{3}{4}(1-x+x^2) - \frac{x^2(10-5x+x^2)}{8(1-x)} \ln x - \frac{(1-x)^4}{8x} \ln|1-x|, \\ \hat{\delta}_Z^{(2)} &\doteq -\frac{15}{16}(1-x)^2 + \frac{x}{8}(3-4x+x^2) \ln x - \frac{(1-x)^4}{8x} \ln|1-x|,\end{aligned}\tag{36}$$

respectively. For $m_A \gg m_B$ and $m_A \approx m_B$, this reduces to

$$\begin{aligned}\hat{\delta}_W^{(2)} \Big|_{x=0} &\doteq -\frac{5}{8}, & \hat{\delta}_Z^{(2)} \Big|_{x=0} &\doteq -\frac{13}{16}, \\ \hat{\delta}_W^{(2)} \Big|_{x=1} &= \hat{\delta}_Z^{(2)} \Big|_{x=1} = 0,\end{aligned}\tag{37}$$

respectively.

Results in the on-shell scheme

The difference between the contributions to the HVV vertices in the electroweak $\overline{\text{MS}}$ and on-shell schemes is not only due to the universal part discussed in the Section 2, but also due to terms specific to the HVV interactions. To elucidate this point, we rewrite Eq. (28) in the on-shell scheme as

$$\mathcal{L}_{HVV} = 2^{1/4} G_\mu^{1/2} H (1 + \delta_u) \left[2M_W^2 W_\mu^\dagger W^\mu (1 + \delta_W) + M_Z^2 Z_\mu Z^\mu (1 + \delta_Z) \right]. \quad (38)$$

In the case of the HWW coupling, it follows from Eqs. (18,32) that we may identify

$$\delta_W^{(1)} = \hat{\delta}_W^{(1)}, \quad \delta_W^{(2)} = \hat{\delta}_W^{(2)}, \quad (39)$$

where it is understood that the couplings on the right-hand sides are to be expressed in terms of G_μ .

On the other hand, in the case of the HZZ coupling, one needs to take into account the shift in $\hat{c}^2$. At the one-loop order, this does not lead to any change, so that

$$\delta_Z^{(1)} = \hat{\delta}_Z^{(1)}. \quad (40)$$

At two loops, however, an extra contribution arises from the denominator of Eq. (32), so that

$$\begin{aligned} \delta_Z^{(2)} &= \hat{\delta}_Z^{(2)} + \delta_Z^{(1)} \Delta\rho^{(1)} \\ &\doteq -\frac{15}{16}(1-x)^2 + \frac{x}{8}(3-4x+x^2)\ln x - \frac{(1-x)^4}{8x}\ln|1-x| \\ &\quad - \frac{N_c}{8}(1+x) \left[1+x + \frac{2x}{1-x}\ln x \right], \end{aligned} \quad (41)$$

with the limits

$$\delta_Z^{(2)} \Big|_{x=0} \doteq -\frac{13}{16} - \frac{N_c}{8}, \quad \delta_Z^{(2)} \Big|_{x=1} = 0. \quad (42)$$

Finally, we can combine the universal and vertex-specific corrections to obtain the complete one- and two-loop corrections to the Lagrangian of Eq. (38) as

$$\begin{aligned} \delta_V^{\text{tot}(1)} &= \delta_u^{(1)} + \delta_V^{(1)}, \\ \delta_V^{\text{tot}(2)} &= \delta_u^{(2)} + \delta_V^{(2)} + \delta_u^{(1)} \delta_V^{(1)}, \end{aligned} \quad (43)$$

respectively. At one loop, we recover the results of Ref. [8, 10]. This completes the discussion of the HWW and HZZ couplings.

4 Loop-induced interactions

The $H\gamma\gamma$ coupling is mediated via loops of W bosons and charged fermions, while the Hgg coupling is generated by quark loops (see Fig. 3a). These virtual particles do not decouple if their masses are much larger than M_H , since their couplings to the Higgs boson grow with their masses. Therefore, the $H\gamma\gamma$ and Hgg vertices provide devices to count the number of charged and coloured high-mass particles, respectively, which may be too heavy to be produced on their mass shells. Owing to QED-like Ward identities, the leading two-loop electroweak corrections to the $H\gamma\gamma$ and Hgg couplings scale only quadratically with the heavy-fermion masses, i.e. they are of $\mathcal{O}(G_\mu m_F^2)$ relative to the Born approximation. In the next subsection, we will derive the $\mathcal{O}(G_\mu m_F^2)$ correction to the $H\gamma\gamma$ amplitude. The corresponding result for the Hgg coupling can then be readily obtained from this by adjusting the coupling constants and colour factors.

4.1 The $H\gamma\gamma$ coupling

For simplicity, we will assume that all three external legs are on their mass shells and that the mass hierarchy $M_H/2 \ll M_W \ll m_F$ holds. Thus, our results should be valid for an intermediate-mass Higgs boson. By virtue of electromagnetic gauge invariance, the $H\gamma\gamma$ amplitude must be proportional to $(k_1 \cdot k_2 g^{\mu\nu} - k_2^\mu k_1^\nu)$, where k_1 , k_2 and μ , ν are the four-momenta and Lorentz indices of the two photons, respectively. We first consider the one-loop contribution due to a weak isodoublet of ultraheavy fermions, with masses m_A , m_B , electric charges Q_A , Q_B and colour multiplicity N_c . At one loop, the effective Lagrangian describing the resulting $H\gamma\gamma$ interaction reads in bare form [23, 33]

$$\mathcal{L}_{H\gamma\gamma} = \frac{e_0^2}{24\pi^2} \frac{H_0}{v_0} F_{0\mu\nu} F_0^{\mu\nu} \sum_{F=A,B} N_c Q_F^2, \quad (44)$$

where e is the electromagnetic coupling constant and $F_{\mu\nu}$ is the electromagnetic field-strength tensor. Up to terms of $\mathcal{O}(\epsilon)$, the corresponding coefficient of $(k_1 \cdot k_2 g^{\mu\nu} - k_2^\mu k_1^\nu)$ is thus given by

$$A_F^{(1)} = -\frac{8}{3v_0} \frac{e_0^2}{16\pi^2} \sum_{F=A,B} N_c Q_F^2 \left(\frac{\mu}{m_{F0}} \right)^{2\epsilon} [1 + \mathcal{O}(\epsilon^2)]. \quad (45)$$

The contributions due to light fermions are negligible.

The residual one-loop contributions, due to W bosons, charged pseudo-Goldstone bosons (ϕ) and Faddeev-Popov ghosts, are conveniently calculated in a non-linear gauge [39, 40], which has frequently been used to simplify the calculation of loop amplitudes

involving external photons [41]. An equivalent alternative makes use of the background-field method [32, 42]. In the non-linear gauge, the $\gamma W^\pm \phi^\mp$ coupling, which is characteristic for the R_ξ gauge, is avoided, so that the photon separately couples to W and charged Goldstone bosons. As a consequence, the bosonic $H\gamma\gamma$ loop diagrams come in a smaller number than in the R_ξ gauge, and they can be separated in W -boson and unphysical-scalar-boson parts. Further modifications [43] in the Faddeev-Popov sector of the SM do not affect the calculation, as ghosts do not couple to fermions. As the $H\phi^+\phi^-$ coupling is proportional to M_H , the diagrams involving the Goldstone bosons can be discarded in our approximation. Keeping the $\mathcal{O}(\epsilon)$ parts and fixing the gauge-parameter to one, we have for the two remaining contributions [32, 41]:

$$\begin{aligned} A_W^{(1)} &= \frac{2}{v_0} \frac{e_0^2}{16\pi^2} \left(\frac{\mu}{M_W^0} \right)^{2\epsilon} \left[\frac{20}{3} + \frac{2}{3}\epsilon + \mathcal{O}(\epsilon^2) \right], \\ A_{FP}^{(1)} &= \frac{2}{v_0} \frac{e_0^2}{16\pi^2} \left(\frac{\mu}{M_W} \right)^{2\epsilon} \left[\frac{1}{3} + \mathcal{O}(\epsilon^2) \right]. \end{aligned} \quad (46)$$

The full $H\gamma\gamma$ amplitude to one loop is then obtained as $A^{(1)} = A_F^{(1)} + A_W^{(1)} + A_{FP}^{(1)}$.

We now turn to the leading two-loop correction to the $H\gamma\gamma$ amplitude. One may wonder whether the Yukawa Lagrangian characterizing the gaugeless limit of the SM [30], which we have used in the previous sections to calculate $\mathcal{O}(G_\mu^2 m_F^4)$ corrections to the $Hf\bar{f}$ and HVV couplings, is sufficient to also extract the $\mathcal{O}(G_\mu m_F^2)$ correction to the $H\gamma\gamma$ coupling. In fact, in contrast to the previous cases, Ward identities insure the absence of $\mathcal{O}(G_\mu m_F^4)$ contributions, and it is not obvious any more that diagrams involving virtual W bosons may be neglected. This can be understood in the following way. After integrating out the heavy fermions, we have two dimension-four operators which produce $\mathcal{O}(G_\mu m_F^2)$ corrections to the $H\gamma\gamma$ amplitude at the two-loop level, namely the operator in Eq. (44) and the first one in Eq. (28), through the diagram of Fig. 3b. Hence, the effective Lagrangian appropriate for the problem at hand is

$$\mathcal{L}_{H\gamma\gamma} = \frac{H_0}{v_0} \left(c_1 F_{0\mu\nu} F_0^{\mu\nu} + c_2 M_{W0}^2 W_{0\mu}^\dagger W_0^\mu + \dots \right), \quad (47)$$

where the ellipsis stands for additional operators involving charged pseudo-Goldstone bosons, such as $\partial_\mu \phi^\dagger \partial^\mu \phi$, which are characteristic for the covariant gauges and are absent in the unitary gauge; for a detailed discussion of the low-energy effective Lagrangian of the SM, see e.g. Ref. [44]. For the problem at hand, we only need the one-loop result for c_2 , which is available from Section 3. By contrast, c_1 must be determined by an explicit two-loop calculation. As in the previous sections, this calculation can be performed by considering the diagrams which only involve virtual Goldstone bosons along with the heavy fermions. The diagrams containing only virtual heavy fermions and scalar bosons are described by a Yukawa Lagrangian in which the would-be Goldstone bosons

are minimally coupled to the photon. Once the relevant two-loop contribution to the photon self-energy function has been calculated from this Lagrangian, one can derive the corresponding $H\gamma\gamma$ vertex correction using a low-energy theorem similar to Eq. (30). We have verified that the photon self-energy tensor, supplemented by the scalar-boson mass counterterms as explained in Section 2, is transverse and satisfies the QED Ward identity. Note that $\Pi'_{\gamma\gamma}(0)$, where $\Pi_{\gamma\gamma}(q^2)$ is the photon self-energy function, contains contributions which depend logarithmically on the scalar-boson masses m_ϕ . Thus, they are infrared divergent in the limit $m_\phi \rightarrow 0$ and gauge dependent in the R_ξ gauges. However, in our approximation of neglecting all scalar-boson couplings to the Higgs boson, the degree of convergence of the irreducible vertex diagrams is higher than the one of the photon self-energy, so that the application of the low-energy theorem leads to an infrared- and ultraviolet-finite and gauge-invariant result for the $H\gamma\gamma$ amplitude.¹

Let us first consider the diagrams in the first row of Fig. 2b, in which both photons couple to the heavy fermions. With the help of the low-energy theorem (30), their contribution to the irreducible $H\gamma\gamma$ vertex is found to be

$$A_\phi^{(2)I} \doteq \frac{1+x}{3\epsilon}(Q_A - Q_B)^2 - \frac{1}{9}(4Q_A^2 + Q_A Q_B - 23Q_B^2) + \frac{x}{9}(23Q_A^2 - Q_A Q_B - 4Q_B^2) + \frac{2}{3}(1+x)Q_B(Q_A - Q_B)\ln x. \quad (48)$$

Here and henceforth, the symbol $\doteq$ indicates that the right-hand side is to be multiplied by the overall factor

$$\frac{N_c e^2 \hat{g}^3 m_A^2}{(16\pi^2)^2 M_W^3} \left(\frac{\mu}{m_A} \right)^{4\epsilon}. \quad (49)$$

The electric charges of the isodoublet partners satisfy the relation $Q_A - Q_B = 1$. We note in passing that, if $Q_A = Q_B$ was fulfilled, Eq. (48) would be ultraviolet finite and free of singularities in the limit of one fermion mass vanishing. In fact, as we will see in the next subsection, this corresponds to the Hgg case.

Next, we consider the diagrams in the second row of Fig. 2b, where the photons couple at least to one charged scalar boson. Also including the contributions due to the scalar-boson mass counterterms, we find

$$A_\phi^{(2)II} \doteq -\frac{1+x}{3\epsilon}(Q_A - Q_B) + \frac{(1+x)}{18}(1 - 5Q_A + 5Q_B)$$

¹As $\Pi'_{\gamma\gamma}(0)$ is infrared divergent even after subtracting the scalar-boson mass counterterms, particular care must be exercised in regularizing these divergences. Logarithmic divergences which have the form $\ln m_\phi$ if we introduce a small mass regulator m_ϕ , turn into $1/\epsilon - \ln m_F$ if we use dimensional regularization. The additional $\ln m_F$ terms introduced in this way conflict with the use of the low-energy theorem (30), which leads one to also differentiate such terms with respect to m_F . Therefore, dimensional regularization of the infrared divergences should be avoided here.

$$-\frac{\ln x}{3(1-x)}[2Q_B + (1 - Q_A - Q_B)x^2] - \frac{1+x}{3}(1 - Q_A + Q_B) \ln \frac{m_\phi^2}{m_A^2}. \quad (50)$$

Due to $Q_B = Q_A - 1$, this is convergent as $m_\phi \rightarrow 0$ and cancels the ultraviolet divergence of Eq. (48). We still need to take into account the counterterm contribution which arises by shifting the bare heavy-fermion masses in Eq. (45) according to Eq. (9), which reads

$$A_\phi^{\text{ct}} \doteq -(1-x)(Q_A^2 - Q_B^2). \quad (51)$$

We recall that the renormalization of e does not generate any $\mathcal{O}(G_\mu m_F^2)$ corrections. Adding Eqs. (48,50,51), we obtain the final result for the scalar-boson exchange diagrams,

$$A_\phi^{(2)} \doteq \frac{10}{3} - 7Q_A + 2Q_A^2 - x \left(\frac{5}{3} - 3Q_A - 2Q_A^2 \right), \quad (52)$$

which is finite and gauge invariant.

Let us now turn to the diagrams involving W bosons. With our choice of gauge, we can separately consider the diagrams which, in addition to the heavy fermions, contain W and charged Goldstone bosons because the $\gamma W^\pm \phi^\mp$ coupling is absent. The W and charged Goldstone bosons still mix through the $HW^\pm \phi^\mp$ coupling, but the leading contribution from the two-loop $H\gamma\gamma$ diagrams which involve this coupling can be removed by an appropriate choice of renormalization in the unphysical sector [36], which respects the Slavnov-Taylor identities [45]. The same choice also insures that M_W in the expression for A_{FP} in Eq. (46) does not need to be renormalized. The only diagrams containing virtual W bosons which can generate $\mathcal{O}(G_\mu m_F^2)$ corrections are those with a quadratic subdivergence. This includes the diagrams where a fermion loop is inserted into a W -boson line. In this case, however, the quadratic subdivergences are cancelled by the corresponding W -boson mass counterterms. We are then just left with the contribution from the left diagram in Fig. 3b, which corresponds to the insertion of the second operator in the effective Lagrangian (47) into the one-loop seed diagram containing a W -boson loop. This contribution can be easily calculated from Eqs. (32,46) and reads

$$A_W^{(2)} \doteq -\frac{10}{3}(1+x). \quad (53)$$

This includes the W -boson mass-counterterm contribution that arises from $A_W^{(1)}$, and has been confirmed by an explicit two-loop calculation.

Finally, we need to include the finite contribution due to the shift in the ratio H_0/v_0 , i.e. $\hat{\delta}_u^{(1)}$ of Eq. (7) in the electroweak $\overline{\text{MS}}$ scheme and $\delta_u^{(1)}$ of Eq. (24) in the on-shell scheme. This is the only scheme-dependent contribution at the two-loop level. As H_0/v_0 is an overall factor common to all one-loop contributions, the shift operates on the total

one-loop amplitude, giving the contributions

$$\begin{aligned}\hat{A}_u^{(2)} &\doteq \frac{2}{3}(1+x) \left(\frac{7}{4} - \frac{1}{3} \sum_F N_c Q_F^2 \right), \\ A_u^{(2)} &\doteq \left[\frac{7}{6}(1+x) + \frac{x}{1-x} \ln x \right] \left(\frac{7}{4} - \frac{1}{3} \sum_F N_c Q_F^2 \right)\end{aligned}\quad (54)$$

in the $\overline{\text{MS}}$ and on-shell schemes, respectively.

The total $\mathcal{O}(G_\mu m_F^2)$ correction $A^{(2)}$ to the $H\gamma\gamma$ amplitude is then obtained by summing the contributions of Eqs. (52–54). In the on-shell scheme, the result reads

$$A^{(2)} \doteq A_u^{(2)} - Q_A(7 - 2Q_A) - x(1 - Q_A)(5 + 2Q_A). \quad (55)$$

In the limiting cases $m_A \gg m_B$ and $m_A \approx m_B$, this reduces to

$$A^{(2)} \Big|_{x=0} \doteq \frac{49}{24} - 7Q_A + 2Q_A^2 - \frac{7}{18}N_c(1 - 2Q_A + 2Q_A^2), \quad (56)$$

$$A^{(2)} \Big|_{x=1} \doteq -\frac{8}{3} - 4Q_A + 4Q_A^2 - \frac{4}{9}N_c(1 - 2Q_A + 2Q_A^2), \quad (57)$$

respectively. Notice, however, that Eq. (56) is only valid in the case of two ultraheavy fermions with a strong mass hierarchy, i.e. $M_W \ll m_B \ll m_A$, and thus cannot be applied to the contribution from the top and bottom quarks. In the latter case, $m_b \ll M_W \ll m_t$, the bottom quark decouples from the one-loop result, so that Eqs. (51,54) must be modified. Then, Eq. (56) becomes

$$A_{tb}^{(2)} \doteq \frac{25}{24} - 5Q_t + Q_t^2 - \frac{7}{18}N_c Q_t^2. \quad (58)$$

In the three-generation SM with $M_H/2 \ll M_W \ll m_t$, the $\mathcal{O}(G_\mu m_t^2)$ -corrected $H\gamma\gamma$ amplitude, renormalized according to the on-shell scheme, reads

$$A_{\text{SM}} = \frac{\alpha G_\mu^{1/2}}{\pi 2^{3/4}} \frac{47}{9} \left[1 + \frac{G_\mu}{8\pi^2 \sqrt{2}} \left(-\frac{511}{94} m_t^2 \right) \right], \quad (59)$$

where $\alpha = e^2/(4\pi)$ is Sommerfeld's fine-structure constant. Large logarithmic QED corrections can be avoided by taking α to be the running coupling evaluated at a renormalization scale of the order of the heavy-quark mass. Should the SM be extended by a sequential fermion generation consisting of a Dirac neutrino N , a charged lepton E , an up-quark U and a down-quark D , with masses $m_N, m_E, m_U, m_D \gg M_W$, then their effects

on $A^{(1)}$, $A^{(2)}$ and $\delta_u^{(1)}$ would come in addition to the respective top-quark contributions. Thus, Eq. (59) would be modified to become

$$A_{4\text{gen}} = \frac{\alpha G_\mu^{1/2}}{\pi^{23/4}} \frac{5}{3} \left[1 + \frac{G_\mu}{8\pi^2 \sqrt{2}} \left(-\frac{49}{2} m_t^2 + \frac{7}{6} m_N^2 - \frac{65}{6} m_E^2 - \frac{m_N^2 m_E^2}{m_N^2 - m_E^2} \ln \frac{m_N^2}{m_E^2} \right. \right. \\ \left. \left. - \frac{237}{10} m_U^2 - \frac{117}{10} m_D^2 - 3 \frac{m_U^2 m_D^2}{m_U^2 - m_D^2} \ln \frac{m_U^2}{m_D^2} \right) \right]. \quad (60)$$

All previous results for the $H\gamma\gamma$ amplitude were derived under the assumption that $M_H \ll 2M_W$. A convenient way to perform the calculation without this restriction would be to employ an effective-Lagrangian approach, and to calculate the contributions of the various diagrams as insertions of appropriate operators whose coefficient functions incorporate the low-energy effect of the heavy fermions. We recall that, in a covariant gauge, the Lagrangian (47) is supplemented by additional operators involving charged pseudo-Goldstone bosons. Similarly to the use of the second operator in Eq. (47) for the diagram of Fig. 3b, they will only enter the calculation through insertions in one-loop diagrams. Therefore, their Wilson coefficients are only needed to $\mathcal{O}(G_\mu m_F^2)$. The only operator whose matching is needed at the two-loop order is the first one in Eq. (47). As only the diagrams in the first row of Fig. 2b do not have a counterpart in the effective theory, this matching is uniquely fixed by Eqs. (48,51), which exhaust all necessary genuine two-loop calculations. If the restriction $M_H \ll 2M_W$ is abandoned, $A_W^{(1)}$, $A_{FP}^{(1)}$ and the corresponding amplitude for the charged pseudo-Goldstone bosons will be multiplied by non-analytic functions of M_H/M_W whose limits for $M_H \rightarrow 0$ are either unity or zero; see, for example, Refs. [4, 32].

In this paper, we do not consider the $\mathcal{O}(G_\mu^2 m_F^4)$ correction to the $H\gamma Z$ coupling. At one loop, the fermionic contribution to the $H\gamma Z$ amplitude is greatly suppressed against the W -boson contribution, and it is likely that this trend carries over to the two-loop order. Furthermore, from the phenomenological point of view, this coupling is much less important than the $H\gamma\gamma$ and Hgg couplings. The $\mathcal{O}(G_\mu^2 m_F^4)$ correction to the $H\gamma Z$ coupling could be calculated along the same lines as those for the $H\gamma\gamma$ coupling, but choosing a different kind of non-linear gauge. In fact, it is possible to fix the gauge in such a way that the $ZW^\pm\phi^\mp$ vertex is avoided, so that the Z boson separately couples to the W and charged Goldstone bosons separately. As in the $H\gamma\gamma$ case, modifications in the Faddeev-Popov sector would not affect the calculation.

4.2 The Hgg coupling

We now study the two-loop $\mathcal{O}(G_\mu m_F^2)$ corrections to the Hgg coupling. They can be inferred from those $H\gamma\gamma$ diagrams where the photons are directly coupled to the loop

fermions. The relevant amplitudes are those given by Eqs. (45,48,51) as well as the term proportional to N_c in Eq. (54). We need to identify $Q_A = Q_B = 1$ and substitute $\alpha \rightarrow \alpha_s$. Furthermore, we need to adjust the overall colour factor by putting $N_c \rightarrow \delta^{ab}/2$ in Eqs. (45,49). Here, a and b are the colour indices of the two gluons. In the following, we shall factor out δ^{ab} along with $(k_1 \cdot k_2 g^{\mu\nu} - k_2^\mu k_1^\nu)$.

In the three-generation SM with $M_H \ll 2m_t$, the $\mathcal{O}(G_\mu m_t^2)$ -corrected Hgg amplitude, renormalized according to the electroweak on-shell scheme, is thus found to be

$$G_{\text{SM}} = -\frac{2^{1/4}\alpha_s G_\mu^{1/2}}{3\pi} \left[1 + \frac{G_\mu m_t^2}{8\pi^2 \sqrt{2}} \left(\frac{7}{6} N_c - 3 \right) \right], \quad (61)$$

where $N_c = 3$, in agreement with Ref. [23]. If the SM was extended by a sequential fermion generation consisting of a Dirac neutrino N , a charged lepton E , an up-quark U and a down-quark D , with masses $m_N, m_E, m_U, m_D \gg M_H/2$, then Eq. (61) would become

$$G_{4\text{gen}} = -\frac{2^{1/4}\alpha_s G_\mu^{1/2}}{\pi} \left\{ 1 + \frac{G_\mu}{8\pi^2 \sqrt{2}} \left[\left(\frac{7}{6} N_c - 1 \right) m_t^2 + \frac{7}{6} (m_N^2 + m_E^2) - \frac{m_N^2 m_E^2}{m_N^2 - m_E^2} \ln \frac{m_N^2}{m_E^2} \right. \right. \\ \left. \left. + \left(\frac{7}{6} N_c - 2 \right) (m_U^2 + m_D^2) - N_c \frac{m_U^2 m_D^2}{m_U^2 - m_D^2} \ln \frac{m_U^2}{m_D^2} \right] \right\}. \quad (62)$$

Here, we have also assumed that $M_H \ll 2m_t$, so that the lowest-order amplitude receives equal contributions from the top, U and D quarks. The heavy leptons N and E only contribute through the renormalizations of the Higgs-boson wave-function and the vacuum expectation value. It is amusing to observe that a mass-degenerate heavy-quark isodoublet does not generate any dominant two-loop correction to the Hgg amplitude. If we eliminate the top-quark and heavy-lepton contributions from Eq. (62) so as to isolate the contribution due to a heavy-quark isodoublet, then we recover the corresponding result of Ref. [23].

5 Discussion

We considered the possible extension of the SM by a sequential heavy-fermion generation and analyzed, at two loops in electroweak perturbation theory, the resulting shifts in the couplings of a light Higgs boson to the SM leptons, light quarks, intermediate bosons, photons and gluons. In the cases of the tree-level and loop-induced couplings, these corrections are of relative orders $\mathcal{O}(G_\mu^2 m_F^4)$ and $\mathcal{O}(G_\mu m_F^2)$, respectively, where m_F is a generic heavy-fermion mass, with $m_F \gg M_W, M_H$. In the $H\gamma\gamma$ case, we also assumed

that $M_H \ll 2M_W$. We obtained the corresponding top-quark-induced corrections of the three-generation SM as special cases.

In the following, we analyze the numerical significance of our results, in the electroweak on-shell scheme. To $\mathcal{O}(G_\mu m_F^2)$ and $\mathcal{O}(G_\mu^2 m_F^4)$, the shifts in the $Hf\bar{f}$, HWW and HZZ couplings due to an isodoublet of heavy fermions, A and B , can all be cast into the generic form

$$\delta = N_c \frac{G_\mu m_A^2}{8\pi^2 \sqrt{2}} C_1 \left(\frac{m_B}{m_A} \right) \left\{ 1 + \frac{G_\mu m_A^2}{8\pi^2 \sqrt{2}} \left[C_2 \left(\frac{m_B}{m_A} \right) + N_c C_3 \left(\frac{m_B}{m_A} \right) \right] \right\}, \quad (63)$$

where C_i ($i = 1, 2, 3$) are dimensionless functions of m_B/m_A and $N_c = 1$ (3) if A and B are leptons (quarks). Also $\Delta\rho$ can be written in this form, with $C_3 = 0$. Since, in the high- m_F limit, $\Delta\rho$, δ_u , δ_W and δ_Z are symmetric in m_A and m_B , we may, without loss of generality, assume that $m_B/m_A \leq 1$. The specific forms of the prefactors in Eq. (63) are chosen in such a way that, in the case of the leading m_t -dependent contribution to $\Delta\rho$, the familiar values $C_1(0) = 1$ [29] and $C_2(0) = 19 - 2\pi^2 \approx -0.739$ [38] are recovered. Relative to $m_t = 175.6$ GeV, we have $N_c G_\mu m_A^2 / (8\pi^2 \sqrt{2}) \approx 0.966\% \times (m_A/m_t)^2$.

The outcome of this decomposition is displayed in Table 1, where the coefficients C_i are listed as functions of m_B/m_A for $\Delta\rho$, δ_u , δ_W^{tot} and δ_Z^{tot} . Let us first discuss the signs of the various terms. The $\mathcal{O}(G_\mu m_F^2)$ terms are throughout positive for $\Delta\rho$ and δ_u , while they are negative for δ_W^{tot} and δ_Z^{tot} . In the case of δ_u , the $\mathcal{O}(G_\mu^2 m_F^4)$ term always enhances the one-loop correction, while in the other cases this depends on the mass ratio and on whether leptons or quarks are considered. From the entries for $m_B/m_A = 0$ in Table 1, we read off that the $\mathcal{O}(G_\mu m_t^2)$ corrections to $\Delta\rho$, δ_u , δ_W^{tot} and δ_Z^{tot} amount to 0.966%, 1.13%, -0.805% and -0.805%, respectively, and that these values receive relative corrections of -0.238%, 2.42%, 3.19% and 6.67% due to the $\mathcal{O}(G_\mu^2 m_t^4)$ terms. On the other hand, a mass-degenerate fourth-generation quark isodoublet, with masses $m_U = m_D = 2m_t$, would not influence the ρ parameter, but induce in δ_u , δ_W^{tot} and δ_Z^{tot} one-loop corrections of 5.15%, -10.3% and -10.3%, respectively, which would be enhanced in magnitude by 11.6%, 1.93% and 1.93% by the two-loop corrections; see right-most entries in Table 1.

The partial widths of the Higgs-boson decays into pairs of SM leptons, quarks and intermediate bosons receive the overall correction factors $(1 + \delta)^2$, where δ is of the generic form (63). In Refs. [14, 15], it was shown how the corresponding corrections to more complicated Higgs-boson decay and production processes may be composed from the elementary building blocks $\Delta\rho$, δ_u , δ_W^{tot} and δ_Z^{tot} .

We now quantitatively discuss the $H\gamma\gamma$ and Hgg couplings and how they are affected by their $\mathcal{O}(G_\mu m_F^2)$ corrections. From Eqs. (59) and (61), we read off that, in the three-generation SM, the $\mathcal{O}(G_\mu m_t^2)$ corrections to these couplings amount to -1.75% and 0.161%, respectively. In the presence of a sequential high-mass fermion generation, the lowest-order $H\gamma\gamma$ and Hgg amplitudes would be multiplied by factors of $15/47 \approx 0.319$

Table 1: Coefficients C_1 (upper entries), C_2 (middle entries) and C_3 (lower entries) in Eq. (63) as functions of m_B/m_A for $\Delta\rho$, δ_u , δ_W^{tot} and δ_Z^{tot} in the electroweak on-shell scheme.

m_B/m_A	0	0.2	0.4	0.6	0.8	1
$\Delta\rho$	1	0.772	0.462	0.211	0.053	0
	-0.739	0.050	1.326	2.423	2.916	3
	0	0	0	0	0	0
δ_u	1.167	1.079	1.004	1.012	1.120	1.333
	3.969	4.696	5.028	4.241	3.139	3
	1.179	1.123	1.151	1.329	1.628	2
δ_W^{tot}	-0.833	-1.001	-1.316	-1.708	-2.160	-2.667
	6.444	4.629	2.449	0.633	-0.767	-1.5
	1.150	1.032	0.892	0.824	0.857	1
δ_Z^{tot}	-0.833	-1.001	-1.316	-1.708	-2.160	-2.667
	10.044	7.748	4.445	1.568	-0.528	-1.5
	3.550	2.636	1.707	1.159	0.937	1

and 3, respectively; see Eqs. (60,62). Consequently, the $H \rightarrow \gamma\gamma$ ($H \rightarrow gg$) partial decay width would be reduced (amplified) by roughly one order of magnitude. If $m_N = m_E = m_U = m_D = 2m_t$, then these modified lowest-order amplitudes would receive two-loop corrections of -71.1% and 2.52% , respectively. The fact that, in the new-physics scenario considered here, the $\mathcal{O}(G_\mu m_F^2)$ correction to the $H\gamma\gamma$ coupling is so sizeable may cast some doubts on the validity of electroweak perturbation theory in this case. By the same token, one could place upper mass bounds on the fourth-generation fermions by requiring that the $\mathcal{O}(G_\mu m_F^2)$ corrections stay perturbatively small. However, one should bare in mind that, due to the negative interference of the bosonic and fermionic diagrams, the one-loop $H\gamma\gamma$ amplitude is substantially reduced by the inclusion of the fourth-generation fermions, so that it may be misleading to use as a criterion the size of the two-loop correction relative to the one-loop result.

ACKNOWLEDGEMENTS

We are grateful to P.A. Grassi for many instructive discussions and to G. Degrandi and F. Feruglio for interesting conversations. One of us (A.D.) thanks the Max-Planck-Institut für Physik for the kind hospitality extended to him during a visit when this paper was finalized.
